**ABSTRACT**

There is a developing interest in *Hemibagrus nemurus* culture. Most hatcheries depend on fry from the wild, which is under threat due to human activities. Hatchery production of *H. nemurus* is not well established due to problems associated with artificial propagation. Good egg quality is essential for fry production. This paper reports the findings of research conducted to determine the effects of mammalian gonadotropin releasing hormone analogue (GnRHa) and ovaprim on induced spawning performance and egg quality of *H. nemurus*. Mature female *H. nemurus* were treated with 0.5ml of 0.7% NaCl (control), 5μg/kg, 20μg/kg, 50μg/kg body weight (BW) of fish GnRHa and 0.5ml/kg BW of fish of ovaprim (20μg/ml sGnRHa and 10mg/ml domperidone). The results showed that the administration of 5μg/kg BW GnRHa is not sufficient to induce the spawning of *H. nemurus*. The egg quality of fish treated with GnRHa at doses 20μg/kg and 50μg/kg were numerically different, however, there was no significant difference (*P*>0.05). Ovaprim treated fish produced the best results. Ovulatory response ranged from 50.0% to 66.7% among all the treatments with high fertilization rate (94-95%). The highest hatching rate (78.3%) and percentage of normal larvae (68.8%) was observed from ovaprim injected fish. The results indicated that 20μg/kg and 50μg/kg BW GnRHa were effective in inducing ovulation and spawning in *H. nemurus* and ovaprim can be recommended to be used by hatcheries to induce *H. nemurus* for spawning. The major significance of this work was 5μg/kg dose of GnRHa is ineffective for ovulation in *H. nemurus*.

INTRODUCTION
Gonadotropin releasing hormone analogue (GnRHa) has been successfully used in the induced spawning of several fish species (Zohar and Mylonas, 2001; Rainis and Ballestrazzi, 2005). In some fish, dopamine prevents the release of gonadotropin through inhibitory actions on the pituitary in the endocrine system, thereby making it impossible for fish to ovulate and spawn. Pre-spawn fish exhibiting dopaminergic tone were induced to spawn using GnRHa in combination with dopamine antagonist like metoclopramide, haloperidol, pimozide and domperidone. Successful spawning of some fish species were achieved using this technique. GnRHa and metoclopramide (Drori et al., 1994), GnRHa and haloperidol (Arabaci and Sari, 2004), GnRHa and pimozide (Tan-Fermin et al., 1997; Park et al., 2007) and GnRHa and domperidone (Manosroi et al., 2004; Sahoo et al. 2005) were reported to be successful to induce ovulation and spawning in fish.

Hemibagrus nemurus is a tropical freshwater catfish that belongs to the Family Bagridae and widely distributed in Asian countries which include: Thailand, Laos, Cambodia, Vietnam, Indonesia and Malaysia (Rainboth, 1996). It is economically important for aquaculture and fisheries; and nutritionally valued for low cholesterol, high protein and omega-3 poly unsaturated fatty acid (Mesomya et al., 2002). Due to the high demand of the fish for food, most of the natural stocks of fish species are being depleted as a result of man’s activities and environmental degradation. There are few government and private hatcheries practising artificial propagation of this fish, and the broodstocks are mostly obtained from the wild. The intensive and commercial culture of H. nemurus is not well established due to the problems associated with induced spawning, some of which include simultaneous maturation of both male and female fish and availability of high quality broodstocks (Muchlisin et al., 2004). Interest in the aquaculture industry of H. nemurus is developing (Khan et al., 1990), thus there is a need to intensify studies on the reproductive biology of H. nemurus so as to be able to use such information for aquaculture production and management.

Khan et al. (1990) provided baseline data for induced breeding of this fish, such as fecundity, gonadosomatic index (GSI) and seasonal variations of oocyte diameters. Besides, Christianus et al. (1998, 1999) presented information on the reproductive biology of male H. nemurus with respect to gonadal development.

Spawning performance is an important indicator for successful induced breeding programme. Thus, this study was attempted to determine the effect of GnRHa and ovaprim on the spawning performance and egg quality of H. nemurus.

MATERIALS AND METHODS
Experimental Animals and Maintenance
One hundred adult male and female H. nemurus collected from the wild (Pahang
River, Pahang, Malaysia) were used for this experiment. Fish body weight ranged from 440 - 900g and standard length measured ranged from 30.5 to 39.4cm. Upon arrival the fish were disinfected with potassium permanganate and kept in 40 tonnes flow-through concrete rectangular tanks under natural photoperiod and temperature for acclimatization. Fish were fed at a rate of 3% body weight to satiation with commercial pelleted feed containing 38 - 40% crude protein, 3% crude fat, 6% fiber and 13% moisture. Thirty females and 15 males were randomly selected and transferred into 2 tonnes round fibreglass tanks and were used for the following experiments. Physico-chemical parameters like temperature, dissolved oxygen and pH were monitored and recorded. These parameters were maintained at 27.0 - 27.5°C, 7.72 - 8.02mg/l and 7.74 - 7.80 respectively.

Hormone Preparation and Administration
Hormones (D-Ala⁶-Pro⁹-NET)-LHRH (GnRHa) and ovaprim (sGnRHa and Domperidone) were purchased from Syndel laboratories, Canada. 1mg GnRHa was dissolved in 10ml of 0.7% NaCl solution. The solution was divided into 10 aliquots and each aliquot was stored in 1ml glass vial. (1ml=100μg GnRHa). The hormone was stored in freezer at -20°C until used. Ovaprim was stored at room temperature. Hormones were administered by intramuscular injections below the dorsal fin of the fish.

Fish Selection and Identification
All fish were anaesthetized with clove oil (0.1ml/l) before handling. Mature fish were used for this experiment and were identified by the genital papillae. Males have elongated genital papillae with reddish tip and released milt upon pressing the abdomen, while the females have round genital papillae and were identified by ovarian biopsy. Eggs were collected and examined under microscope for the germinal vesicle (GV) position and oocyte diameter (OD). Fish having oocytes with the GV migrating towards the periphery were selected. These fish were then tagged with coloured plastic tags for easy identification based on treatment groups.

Experimental Design
Both the male and female fish were injected with hormone to induce spermiation and ovulation. The fish were divided into 5 groups. The first group was injected with 0.5ml of 0.7% saline solution and used as a negative control. The second group received 5μg/kg BW GnRHa hormone treatment, the third group 20μg/kg BW GnRHa, the fourth group 50μg/kg BW GnRHa hormone treatment and the fifth group 0.5ml/kg BW of ovaprim (20μg/ml sGnRHa and 10mg/ml domperidone) as a positive control. Each group comprised of 9 fish (6 females and 3 males).

Ovulation rate was measured as the percentage of females that ovulated in a treatment group. Ovulated eggs were checked under the microscope for germinal
vesicle breakdown. Artificial fertilization was carried out using the dry method. Artificial fertilization of spawn from each fish was carried out in triplicates for statistical reasons. Fertilized eggs were incubated in 5 litres plastic tanks. To determine the fertilization rate, 3 subsamples were collected (200 eggs per sample) and embryo at 4-cell division stage was characterized as fertilized. To determine the hatching rate, the subsamples of the fertilized eggs were collected, placed in 1000ml beakers with aeration and observed until hatching. Hatching occurred around 24-28 hours after fertilization. Normal larvae (Fig.1) and abnormal larvae (larvae with deformed body, curved spine, round yolk sac, short and thick body, enlarged fin folds, big yolk sac not proportional to the body) were counted and recorded. Survival rate was determined by counting the number of larvae after 4 days of hatching.

Fig.1. Normal Larvae of *H. nemurus*

Statistical Analysis
All data analyses were carried out using a computer Statistical Analysis Software (SAS). Data were expressed as mean ± standard error of mean. One way analysis of variance (ANOVA) followed by Duncan’s New Multiple Range Test (DMRT) was used for the variation in treatment means and \( P < 0.05 \) was selected as the level of significance.

The following formulas were used to calculate the egg quality parameters:

Ovulatory response = \( \frac{\text{Number that spawn}}{\text{Number induced}} \) \times 100%

Fertilization rate = \( \frac{\text{Number of fertilized eggs}}{\text{Number of eggs incubated}} \) \times 100%

Hatching rate = \( \frac{\text{Number of hatched eggs}}{\text{Number of fertilized eggs}} \) \times 100%

Percentage of normal larvae = \( \frac{\text{Number of normal larvae}}{\text{Number of hatched eggs}} \) \times 100%

Percentage of abnormal larvae = \( \frac{\text{Number of abnormal larvae}}{\text{Number of hatched eggs}} \) \times 100%

Survival rate = \( \frac{\text{Number of larvae after 4 days}}{\text{Number of hatched eggs}} \) \times 100%

RESULTS AND DISCUSSION
Table 1 shows the number of fertilized eggs, hatched eggs, normal larvae, abnormal larvae and survived larvae of induced spawn *H. nemurus*.

There was no ovulatory response in the control and 5μg/kg BW GnRHa groups. This indicated that for a successful induce spawning using GnRHa, higher doses are required. Hence, based on these results, the major significance of this study was that 5μg/kg BW GnRHa dose is ineffective for ovulation in *H. nemurus*. Ovulatory

*Data are mean ± SEM and based on subsamples of 200 eggs.*

**Numbers with the same superscripts in a column are not significantly different (p > 0.05)**

Number of female fish used per treatment = 6

Responses of 50% were observed in fish injected with 20μg/kg BW GnRHa and ovaprim which is the positive control group. When compared to the ovulatory response of wild catfish *Silurus asotus*, GnRHa at doses of 0.01 - 0.02μg/g induced a low ovulation response of 25.0 - 37.5% (Wen and Lin, 2004), but in catfish *Pangasius hypophthalmus*, a higher ovulatory response (88%) was obtained using ovaprim (Legendre et al., 2000). Ovaprim (sGnRHa 20μg/kg) and domperidone (10mg/kg) is ideal for induction of spawning in the Asian catfish *Clarias batrachus* for high ovulatory response (Sahoo et al., 2005). In this study, *H. nemurus* produced a high ovulatory response of 66.7% when treated with 50μg/kg BW GnRHa. On the contrary, 50μg/kg BW GnRHa could not induce ovulation in the Asian catfish *Clarias macrocephalus* (Tan-Fermin et al., 1997) and in the stinging catfish *Heteropneustes fossilis* (Tharakan and Joy, 1996).

A high fertilization rate (94-95%) was obtained with fish injected with 20μg/kg GnRHa, 50μg/kg GnRHa and ovaprim; and fertilization rates were not significantly different (p > 0.05) among these treatments. In this study, ovaprim resulted in the highest fertilization rate (95%). Ovaprim was found to produce high fertilization rate of 98.31% in African catfish *Heterobranchus bidorsalis* (Nwokoye et al., 2007) and 73% in *Pangasius sutchi* (Chand et al., 2011). Thus, indicating that, GnRHa is capable of producing high fertilization rates when used to induce spawn fish.

Hatching rate was significantly different (P<0.05) among all the treatments. A high hatching rate (78.3%) was obtained from fish treated with ovaprim. Ovaprim injected catfish *Pangasius hypophthalmus* resulted in 72 ± 25% hatching rate (Legendre et al., 2000). A high hatching rate (98.35%) was also reported by Nwokoye et al. (2007) in ovaprim treated African catfish.
Heterobranchus bidorsalis. The same hormone produced hatching rate of 60% in Asian catfish Heteropneustes fossilis (Haniffa and Sridhar, 2002). This signifies that ovaprim has a high potential for induced breeding of catfishes producing high hatching rates. In this study, 20μg/kg GnRHα and 50μg/kg GnRHα resulted in hatching rates of 57.2% and 53.3% respectively and there was no significant difference (P > 0.05) in the hatching rate of H. nemurus treated with 20μg/kg and 50μg/kg GnRHα. Some catfishes require higher doses of GnRHα to spawn. A higher dose of 100μg/kg GnRHα was used in channel catfish Ictalurus punctatus, and hatching rate of 69±5% was recorded (Silverstein et al., 1999).

The percentage of normal larvae obtained from the different treatments was significantly different (P<0.05). The highest percentage of normal larvae (68.8%) was obtained using ovaprim, followed by 50μg/kg GnRHα (58.1%) and 20μg/kg GnRHα (53.4%). Results of 20μg/kg GnRHα and 50μg/kg GnRHα were not significantly different (P>0.05). This study showed that ovaprim produced the lowest percentage of abnormal larvae. A larval survival rate of 40 - 43% was observed for all the treatments. Similarly, a low survival rate (38%) was observed in ovaprim treated Asian catfish Heteropneustes fossilis (Haniffa and Sridhar, 2002). The low survival rate might be due to some external factors such as water quality, temperature and feeding of larvae. Further studies are needed to investigate the effect of these factors on larvae survival. Thus, based on the findings of this study, it is obvious that in terms of egg quality, ovaprim injected H. nemurus gave the best results. GnRHα injected fish at a dose of 5μg/kg, is not effective in inducing ovulation and spawning, and the results showed that there was no significant difference (P>0.05) in the egg quality of induced spawn H. nemurus using GnRHα at doses of 20μg/kg and 50μg/kg.

CONCLUSION

This study confirms that GnRHα is effective in inducing ovulation and spawning in H. nemurus and can be used in hatcheries for induced breeding. However, a low dose of GnRHα (5μg/kg) may not induce the fish to spawn. Thus, the significance of this research was that 5μg/kg GnRHα can not bring about ovulation in H. nemurus. Induced breeding of this fish in hatcheries will help to reduce pressure on the wild population due to over-harvesting. At the same time, H. nemurus fry produced in hatcheries can be used for wild restocking. Ovaprim injected H. nemurus produced the best spawning performance and egg quality and can be recommended to hatcheries. The spawning performance and egg quality of H. nemurus treated with 20μg/kg GnRHα and 50μg/kg GnRHα were not significantly different. Therefore, it is economical and cost effective to use 20μg/kg GnRHα.
